CALCULUS AND PROBABILITY BASED STATISTICS

MARK ANDREW GERADS

1. Finite statistics

1.1. **Introduction.** The purpose of this text is to have statistics built on a solid foundation of probability and calculus.

Definition 1.1. A is a repeatable event.

Definition 1.2. p is the probability that A will happen when A is given a chance to happen. For simplicity, we assume that p is the same every time A is given a chance to happen.

Definition 1.3. $n \in \mathbb{W}$ is the number of times A had a chance to happen.

Definition 1.4. $k \in \mathbb{W}$ is the number of times A actually happened.

Remark 1.5. $k \leq n$.

Definition 1.6. f_p is the probability is the probability distribution for p.

Remark 1.7. $1 = \int_0^1 f_p \mathrm{d}p$

Definition 1.8. (a, b) is the prediction interval of p such that $b - a$ is minimized.

Definition 1.9. c is the desired certainty for the prediction interval of p.

Remark 1.10. $0 \leq c = \int_a^b f_p \mathrm{d}p \leq 1$

Remark 1.11. $0 \leq a \leq b \leq 1$

Now that we have the definitions, here is the problem: n, k, c are known, and we must solve for a, b.

Remark 1.12. The probability of k events given n chances is $\binom{n}{k} p^k (1-p)^{n-k}$, but we must scale it to satisfy 1.7:

$$f_p = \frac{\binom{n}{k} p^k (1-p)^{n-k}}{\int\limits_0^1 \binom{n}{k} p^k (1-p)^{n-k} \mathrm{d}p} = \frac{p^k (1-p)^{n-k}}{\int\limits_0^1 p^k (1-p)^{n-k} \mathrm{d}p} = (n+1)\binom{n}{k} p^k (1-p)^{n-k} \tag{1.1}$$

1.2. **The 4 cases of finding the interval.**

1.2.1. *Case* $n = k = 0$. This case is self-symmetrical.

Remark 1.13. We have

$$(a, b) = \left(\frac{1-c}{2}, \frac{1+c}{2}\right) \tag{1.2}$$

1.2.2. *Case* $n > k = 0$. This case is symmetrical to case 1.2.3.

Remark 1.14. We can solve

$$\int_a^1 (k+1) p^k \mathrm{d}p = c = 1 - a^{k+1} \tag{1.3}$$

Remark 1.15. We have

$$(a, b) = \left((1-c)^{\frac{1}{k+1}}, 1\right) \tag{1.4}$$

Date: February 19, 2016.

1.2.3. *Case* $n = k > 0$. This case is symmetrical to case 1.2.2.

Remark 1.16. We can solve

$$\int_0^b (k+1)(1-p)^{n-k}\mathrm{d}p = c = \frac{(k+1)\left((1-b)^{-k+n+1}-1\right)}{k-n-1} \tag{1.5}$$

Remark 1.17. We have

$$(a,b) = \left(0, 1-\left(\frac{c(k-n-1)}{k+1}+1\right)^{\frac{1}{-k+n+1}}\right) \tag{1.6}$$

1.2.4. *Case* $n > k > 0$. This case is self-symmetrical.
